

Superstore Sales Assignment — Key Findings

Summary

This document summarizes the key analytical findings drawn from the 11-section Excel workbook built on the Superstore Sales dataset.

Key Findings

- Monthly sales aggregation (SUM, MAX, MIN, SMALL, LARGE, MEDIAN) shows clear peak and low months, with the highest month significantly outperforming the median, indicating seasonal spikes rather than steady demand.
- Sorting and multi-level sorting reveal that a small number of subcategories (e.g. Furniture, Tables) consistently rank at the top for both sales volume and value, suggesting concentration in a handful of product lines.
- Text cleaning and standardization (Find & Replace, Text to Columns) surfaced inconsistent entries in raw fields, confirming the source data required normalization before reliable aggregation was possible.
- Pivot Table grouping by category/subcategory highlights that a few categories account for a disproportionate share of total sales, consistent with the sorting-based finding above.
- Conditional aggregation (SUMIFS/COUNTIFS) across multiple criteria confirms regional and category-level performance varies meaningfully, supporting segmented rather than blanket sales strategy.
- Conditional formatting (icon sets) on trend data flags a mix of improving and declining segments month-over-month, rather than a uniform trend.
- Consolidation of multiple ranges into a single summary view confirms totals reconcile correctly across sheets, validating the integrity of the formulas used throughout the workbook.

Conclusion

Taken together, the analysis points to a sales pattern that is seasonal and concentrated in a small set of top-performing subcategories and regions, rather than evenly distributed. Data quality issues in the raw dataset were identified and resolved through cleaning steps before analysis, and the final consolidated view confirms the figures are internally consistent across the workbook.
